## Binary Representation of Images using Python

Here is a Python program that turns a binary number into an image. The program converts a ' 1 ' into a star and a ' 0 ' into a space:

| $0=" "$ | $1=" * "$ |
| :---: | :---: |

```
#get a binary number from the user
img_in = input("Enter your b&w bitmap image: ")
#initially, there is no output
img_out = ""
#loop through each character in the binary input
for character in img_in:
    #add a star (*) to the output if a 1 is found
    if character == "1":
        img_out = img_out + "*"
    #otherwise, add a space
    else:
        img_out = img_out + " "
#print the image to the screen
print(img_out)
```

Fill out this table, to record what image is printed when you enter some binary numbers. You can also enter some of your own.

| Input | Output |
| :--- | :--- |
| 11001100 |  |
| 10101010 |  |
|  |  |
|  |  |

Modify your program so that it has a display width of 6 characters. You could create a new variable called "position", and add 1 to it for every character the user enters, printing a "newline" whenever the position reaches 6 .

Your program should now work like this:

```
>>>
Enter your b&w bitmap image: 111111100001111111
******
* *
******
```

Fill out this table, to record what image is printed when you enter some 2-bit binary numbers. How many different shapes can you make?

| Input | Output |
| :--- | :--- |
| 111111100001111111 | A hollow rectangle. |
|  | A triangle. |
|  |  |
|  |  |

## Challenge

Can you make a 'colour' display, by using 2 binary bits to store each colour?

| $00=" "$ | $01=" . "$ | $10=" \sim "$ | $11=$ "*" |
| :--- | :--- | :--- | :--- |

A user could then type in something like "00 011011100100 ", which would print " . .*~." You may need to use this line in your code:

```
for char in img_in.split():
```
